ABSTRACT

This paper investigates the nexus among employment, labor productivity and trade openness in Brazil, Russia, India, China, South Africa (BRICS), and Indonesia using annual data (1991–2018). The results suggest a long-run relationship among the variables but only in the agricultural sector of these economies. We also find a unidirectional causality running from employment to productivity in only the agricultural sector. Similarly, trade openness also Granger causes employment. Our final result indicates that trade openness positively influences labor productivity in the long-run. From a policy perspective, it is imperative for BRICS and Indonesia to target employment generation by promoting trade openness.

Keywords: Labor productivity; Trade openness; Sectoral change; Panel cointegration; BRICS; Indonesia.

I. INTRODUCTION

One of the International Labor Organization's global employment agenda is to promote higher productivity and create employment opportunities for countries to improve standards of living and long-term sustainable growth (World Employment Report, 2004-05). Theoretically, labor productivity, employment and output are closely interlinked. This identity implies that, for any given economy, output growth can be achieved with either high productivity and low employment growth or with low productivity growth and high employment growth (Landmann, 2004).

Productivity is a measure of how effectively the economy's resources are translated into the production of goods and services. Over long periods of time, productivity is the single most important determinant of a nation's standard of living (Harris, 2002). On the other hand, employment plays a crucial role in the overall performance of a country. Thus, these two components are the most important indicators of economic growth of a country (Mills, 1952; Padalino and Vivarelli, 1997). According to the marginal productivity theory, high labor productivity leads to high real wages, which improves living standards. However, an increase in output per unit of labor requires more use of capital-intensive production techniques, which leads to mass destruction of employment. On the other hand, higher productivity leads to better technological progress, which improves the efficiency of the production process, allowing firms to produce more output with fewer workers. At the same time, productivity gains lead to employment creation as well, since technology also creates new products and new processes, which lead to the expansion of markets and additional job opportunities (Landmann, 2004; McMillan and Rodrik, 2011).

These two views on labor productivity growth seem contradictory. If higher labor productivity allows firms to get rid of workers, how can it raise the standard of living? Secondly, if technology creates new products, and higher demand for those products creates job opportunities, then, how unemployment rate increases in an economy? The third aspect of this study is trade openness, which has been linked to productivity and employment. The advocates of liberal trade regimes debate that one of the main recipients of greater trade openness are the country's workers.

In developing countries, given excess supply of labor, trade can encourage producers to relocate output in favour of labor-intensive goods. The resulting increase in the demand for labor leads to an increase in employment (Krugman and Lawrence, 1994; Edward, 1998). Trade openness is also the main channel of technology transfers and knowledge spillovers. Edwards (1998) shows a significant relationship between openness and productivity growth; however, an increase in trade openness reduces job destruction (Christev et al., 2008).

The aim of this paper is to undertake a detailed investigation on the nexus between employment, labor productivity and trade openness in selected emerging

countries.¹ The study emphasizes on BRICS and Indonesia because these big emerging countries have achieved remarkable growth and inflows of foreign investment, and have undergone a structural change and substantial reduction in poverty. These six emerging countries also have relatively large population sizes, along with similar features, including structural changes and offer interesting lessons for low income developing countries for their sectoral growth dynamics. Although the bulk of the existing literature focuses on the linkages between either employment and productivity (Bhattacharya and Narayan, 2010; Bhattacharya et al., 2011; McMillan and Rodrik, 2011; Junankar, 2013; Samargandi, 2018; Dinh Long et al., 2019; Moussri and Chatri, 2020), or trade and employment, or trade and productivity (Pieper, 1998; Wacziarg and Wallack, 2013; Greenway et al., 1999; Kucera et al., 2012; Dollar, 1992; Sachs and Warner, 1995; Edwards, 1998; Miller and Upadhyay, 2000; and Soderbom and Tea, 2003), there is hardly any study on the linkages among these three key macroeconomic indicators for these BRICS and Indonesia. Given that these countries have opened up their economies through economic reforms, particularly in 1980s and 1990s, examining the relationship between employment and labor productivity in the presence of trade openness at the sectoral level would further strengthen the debate on employment, trade and productivity nexus.

Against this backdrop, the paper aims to examine the relationships among employment, labor productivity and trade openness for BRICS countries and Indonesia. This paper differs from the earlier works in two novel ways. First, for emerging countries like BRICS and Indonesia, macroeconomic stabilization depends on both productivity and employment, which can adjust per capita income growth and overall inequality. However, little attention has been given to the dynamic adjustment of the economic structure of employment and labor productivity along with the significant trade openness adopted by many developing countries in 1990s and 2000s. Second, here economic structure is defined as the sectoral composition of employment and labor productivity and we examine the nexus between these two variables along with trade openness by considering the agricultural, industrial and service sectors. Industry or manufacturing has long been documented for its role as “leading sector” or “engine of growth” in the development process (Kaldor, 1966). Overall, this paper attempts to verify whether any long-run relationship exists among employment, labor productivity and trade openness for agricultural, manufacturing and service sectors of BRICS and Indonesia.

This study provides the following insights. The results show an existence of a long-run relationship among employment, labor productivity and trade openness

¹ One of the important lessons from the current COVID-19 pandemic is that countries have become more open and, as a result, they have become more susceptible to external shocks like the COVID-19 outbreak; see Akram et al. (2020), Vidya, and Prabheesh (2020), Chen et al. (2020), Devpura (2020), Devpura and Narayan (2020), Iyke (2020a, b, c), Khattak et al. (2020), Liu, Sun and Zhang (2020), Liu, Choo and Lee (2020), Mishra et al. (2020), Narayan (2020a, b, c), Narayan, Devpura and Wang (2020), Narayan, Phan and Liu (2020), Narayan, Gong and Ahmed (2020), Phan and Narayan (2020), Sha and Sharma (2020), Sharma & Sha (2020), and Sharma (2020) for studies exploring the impact of the COVID-19 pandemic on economies). Therefore, understanding how openness affects indicators like employment and productivity is of importance to economic agents.

in the agricultural sector and an absence of any such relationship in the industrial and service sectors. The panel causality results also indicate a unidirectional causality running from employment to productivity in the agricultural sector. Similarly, trade openness also panel Granger causes employment, but the results derived from the long-run estimates indicate that trade openness positively affects labor productivity. Overall, the impact of labor productivity and trade openness on labor markets in BRICS and Indonesia is either minimal or insignificant.

The rest of the paper is in four sections. Section II briefly reviews the literature. Section III presents the theoretical framework, econometrics methodology and data. Section IV presents a preliminary analysis of the sectoral structure and empirical results. Section V draws the conclusions.

II. REVIEW OF LITERATURE

This section discusses why the nexus among employment, productivity and trade liberalization is considered as one of the contentious areas of macroeconomics. We begin by understanding the channels through which productivity may be improved by trade activities—Bloom et al. (2016) provide perhaps the most intuitive explanation. First, trade induces productivity improvements by shifting resources and output from less productive to more productive and efficient firms, and a new technological introduction may play a key role for this productivity and efficiency (see, for example, Melitz and Redding, 2013). This channel is the so-called reallocation effects channel. The second channel is through the impact of trade on innovation, which may arise due to competition (Porter, 1990). More competitive and innovative firms are more likely to survive and become winners in long run. The emergence of China as a global factory and a country that is also endowed with a large market size alongside rising innovation could dominant in world market. The declining trade barriers across countries including EU and US can help high-tech industries to grow relatively faster than low-tech industries, while in case of China the reduction in trade barriers made favorable for low-tech industries to grow further. However, as pointed out by Bloom et al. (2016), the aggregate changes following trade liberalization have occurred *within* rather than *between* industries, and hence there are strong reallocation effects, whereby low-tech firms tend to shrink and exit because of China.

Unlike trade and productivity, the impact of trade on employment is still not clear in the literature. A strand of literature suggests that globalisation and trade openness significantly reduce the equilibrium unemployment rate. This literature features studies such as Melitz (2003), Mitra and Ranjan (2010), and Gozgor (2014) for the case of developed countries. In similar vein, some studies conducted on emerging economies—e.g. Lo Turco and Maggioni (2013) for Turkey, Ridhwan et al., 2015; Simorangkir (2008), Widyasanti (2017), Vidya and Prabheesh (2019) for Indonesia, Joshi and Omkarnath (2020) for India, and Kucera et al. (2012) for India and South Africa—show a synchronized trade and employment between these countries and their trading partners (the European Union and the United States, in particular).

In contrast, another strand of literature casts a doubt on whether trade openness (liberalization) or such a movement from autarky to free trade could really create

jobs (Feenstra, 1998; Ranjan, 2012). Simply speaking, globalisation may increase the long-run unemployment rate (see, for example, Egger and Kreickemeier, 2009; Helpman and Itskhoki, 2010, for developed countries). A recent study by Autor and Dorn (2013) finds a substantial impact of China in reducing US employment since the year 2000, particularly among low-skilled workers (see also, Bloom *et al.* (2016). In contrast, Greenway *et al.* (1999) found that the UK trade volumes with East Asian countries (both in terms of imports and exports) cause reductions in the level of derived labor demand in the UK. This finding is mainly in line with Feenstra and Hanson (1996), who pointed out that trade may also result in the relocation abroad of the most labor-intensive stages of the production process. An interesting study in India by Vashisht (2016) found that, despite the direct impact of trade on employment in the Indian manufacturing sector being positive, the indirect effect of trade on employment has been negative as an increase in export orientation as well as an increase in import penetration have reduced the derived demand for labor; therefore, the overall employment gains from trade tend to be minimal.

So far, the surveyed literature posits bilateral effects between trade openness and productivity as well as between trade and employment. This study, however, attempts to link all these variables together to enhance our knowledge and policy perspectives. The increasing export and import activities following trade liberalization may improve firm productivity due to a shift towards new technology, and in turn a reduction in firm employment. The positive effect of trade on firm employment could also happen via other channels. For example, in Turkey, imports and exports may positively and directly impact a firm's scale of production, thus pushing the firm's demand for labor upward. Also, the improvements in productivity stemming from trade externalities may foster firm competitiveness, which may indirectly lead to growth in firm output and market share. To sum up, despite the contrasting pieces of evidence on the effects of trade on employment and productivity, policy makers in developing countries inevitably, should be concerned about how to upgrade the competitiveness of their domestic firms to enable them penetrate global markets.

III. THEORETICAL FRAMEWORK, METHODOLOGY AND DATA

A. Theoretical Framework

The concept of labor productivity and employment is very much highlighted in Adam Smith's *Wealth of Nations* (Smith, 1776). According to Adam Smith, economic growth is nothing but the sum of labor productivity growth and employment growth. Labor productivity is the main factor in the determination of per head output, while employment growth depends on the structure of the production processes and the type of capital in use (Joshi and Omkarnath, 2020). Similarly, from a theoretical perspective, the Heckscher-Ohlin model and Samuelson (1948) demonstrate the benefits of international trade and its implication on the labor market. Subsequently, Helpman and Itskhoki (2010) demonstrate the linkage between trade openness and the labor market. According to them, trade openness increases a country's rate of unemployment and reduces employment in the presence of market frictions. A theoretical linkage along with a methodological

line for examining the impact of trade and labor productivity on employment in the literature is either through the growth accounting framework or through labor demand equation approach Greenway *et al.* (1999); Vashisht, 2016). In this paper, we follow the growth accounting framework², as the baseline equation, which can be written as:

$$\Delta E_{it} = \Delta_{i1}(1 - S_{i0})\Delta D_i + \Delta X_{it} + \Delta_{i1}(S_{i0} - S_{i1})D_{i1} + \Delta LP_i Q_{i0} \quad (1)$$

where ΔE denotes change in employment, ΔD denotes change domestic consumption, ΔX stands for exports, $LP = L/Q$ is the labor productivity, Q denotes output, S denotes the share of imports in total domestic consumption, i represents i^{th} sector and t refers to time.

B. Methodology

This section outlines the approach to investigating the nexus among employment, labor productivity and trade openness using panel unit root test, panel cointegration and causality tests.³ Further to examining the nexus among these three variables, the study make use of three models, each representing the agricultural, industrial and service sectors.

$$EA_{it} = \alpha_{0i} + \beta_{1i}LPA_{it} + \beta_{2i}TO_{it} + e_{i,t} \quad (2)$$

$$EI_{it} = \theta_{0i} + \delta_{1i}LPI_{it} + \delta_{2i}TO_{it} + u_{i,t} \quad (3)$$

$$ES_{it} = \varphi_{0i} + \lambda_{1i}LPS_{it} + \lambda_{2i}TO_{it} + v_{i,t} \quad (4)$$

where Equations (2), (3) and (4) are Models (I), (II) and (III), respectively; EA_{it} is employment in the agricultural sector, EI_{it} refers to employment in the industrial sector, ES_{it} is employment in the service sector, LPA_{it} refers to labor productivity in the agricultural sector, LPI_{it} is labor productivity in the industrial sector, LPS_{it} stands for labor productivity in the service sector, TO_{it} indicates trade openness, α , θ , and φ are intercepts of the models. Similarly, e , u and v are the error terms, i refers to number of countries and t refers to time period starting from 1991 to 2018.

Before estimating these models, the study first examines the stationary properties of each of the seven variables using a first generation panel unit root test, Im, Pesaran, Shin (2003) test, which assumes no dependence of cross-sectional units as well as a second generation cross-sectional augmented (CIPS) panel unit root test developed by Pesaran (2007). If variables have a unit root at level, then, in the second step, we investigate their long-run relationship using the panel cointegration techniques developed by Pedroni (2004) and Westerlund (2007). The Pedroni (2004) test documents heterogeneity in the intercepts and is considered as a residual based method. Hence, to check the robustness of the test results, the

² See Juhro *et al.* (2020) for an illustration of the growth accounting framework.

³ We thank the reviewer for suggesting that we apply time series tests for each country. However, since T (the number of years) is only 28 years, employing time series cointegration tests may not provide robust results. The study could also not include data prior to 1991, because of unavailability of sectorial employment data for BRICS and Indonesia.

study employs the Westerlund (2007) test. The Westerlund (2007) test is extended to a heterogeneous panel framework and is based on a single equation error-correction models, and hence worth comparing with the Pedroni (2004) test. Third, we employ the panel DOLS estimator proposed by Kao and Chiang (2001) to obtain the long-run elasticity coefficients. The DOLS estimator is relatively better than fully-modified OLS (FMOLS) estimator, particularly in small panels when N and T up to 60. Finally, in the fourth step, to assess the direction of causality, the study employs the Dumitrescu–Hurlin (2012) panel Granger causality test, which is robust to heterogeneity and cross-sectional dependencies in panels (see Dumitrescu and Hurlin, 2012).

C. Data

The study uses annual data for the period from 1991 to 2018 for six emerging countries (i.e. BRICS and Indonesia). The choice of beginning and end periods are purely based on availability of data for all six countries. The study uses data on employment, labor productivity, trade openness, gross value added and per capita gross domestic product (GDP). Further, we collect the employment and labor productivity data for the agricultural, industry and service sectors. Employment in each sector is measured as a percentage of total employment of the economy. The GDP and gross value-added data are in constant 2010 US\$. The gross value added in the agriculture, industry and service sectors are also measured as a shared of total GDP. Labor productivity in each sector is measured as a ratio of gross value added to employment. Trade openness is measured as exports plus imports as a percentage to GDP. All data are collected from the *World Development Indicators* (WDI) database published by the World Bank.

IV. EMPIRICAL RESULTS

A. Preliminary analysis

Table 1 presents the shares of gross value added (GVA), employment and trade openness along with sectoral labor productivity in BRICS and Indonesia during 1991-2018. We begin by presenting the results for Brazil. The share of GVA in the agricultural sector has declined, on the one hand, from 1991 to 2018. However, the share of GVA in the service sector has increased, on the other hand, over the years. By looking at the employment share, the study notes that the service sector plays a dominant role in employment generation as compared to the industrial and agricultural sectors. Trade openness (exports plus imports as a percentage of GDP) has increased from 18.4% during 1991-2000 to 25.5% during 2011-2018. Despite this increase, it is indispensable to say that the trade openness of Brazil is lowest among the six countries. By looking at the labor productivity figures, we notice that the labor productivity in the industrial sector is higher than the labor productivity in the agricultural and service sectors.

Table 1.
Share of Gross Value Added, Employment and Labor Productivity in BRICS and Indonesia

This table presents the average shares of gross value added, employment, and trade openness along with average sector-wise labor productivity in BRICS and Indonesia. The results based on gross value added indicate that the service sector is the dominant sector in BRICS and Indonesia. However, by looking at the employment share, it is clearly visible that the employment share of the service sector is significant in Brazil, Russia and South Africa; however, in Indonesia and India, the bulk of employment is generated by the agricultural sector. The sectoral average labor productivity figures show that labor productivity in the industrial sector is highest in all countries, except India, where labor productivity in the service sector is highest during 2000-2018. Note that GVAA = gross value added in the agricultural sector, GVAI = gross value added in the industrial sector, GVAS = gross value added in the service sector, EA = employment in the agricultural sector, EI = employment in the industrial sector, ES = employment in the service sector, TO = trade openness, PGDP = per capita gross domestic product, LPA = labor productivity in the agricultural sector, LPI = labor productivity in the industrial sector, LPS = labor productivity in the service sector.

2011-2018	2.2	26.4	61.1	5.1	23.5	71.4	61.2	7505.6	43.5	112.2	85.6

Second, we discuss the findings from China. The share of gross value added in the agricultural sector has declined over the years. The GVA share of the industrial sector, which dominated till 2010, has slightly declined (42.7%) during 2011-2018. On the other hand, the GVA share of the service sector has increased consistently from 1991 to 2018. Similarly, the share of employment in the agricultural sector has declined, and the share of employment to total employment in both the industrial and service sectors has increased over the study period. Trade openness, which was on an average 54% during 2001-2010, has declined to 43% during 2011-2018. This clearly reveals that the export and import shares have decelerated, particularly

from 2016 onwards. The labor productivity in the industrial sector is highest in comparison to agricultural and service sectors.

Third, we present the results obtained for India. The share of GVA in the agriculture sector has declined, while the GVA share of the service sector has increased like all the other countries. But it is worthwhile to mention that, despite the decline in the GVA share in India, it is still the highest (16.3% during 2011-2018) among studied countries. The share of GVA in the industrial sector ranges between 27-29% during 1991-2018. By looking at the employment figures, it is clearly evident that the agricultural sector plays a dominant role by absorbing the largest portion of India's labor force, although the share has declined over the years. It is also interesting to note that no other country is the largest proportion of employment still engaged in the agricultural sector as in India. Trade openness has also increased in India over the years. The productivity in the service sector is highest in comparison with the agricultural and industrial sectors.

Fourth, Indonesia being one of the leading emerging countries in the world, has also undergone a structural change. By looking at the GVA figures, the share of the agricultural sector has declined, which is not surprising, but it is worth mentioning that the GVA shares of both the industrial and service sectors equally contribute to the Indonesian economy. Similarly, employment shares in the agricultural sector has declined over the period from 1991 to 2018. However, the shares of employment to total employment in the industrial and service sectors have increased over the years with the service sector representing the leading employment generator in recent years. Trade openness has also drastically declined in Indonesia from 1991 to 2018. The labor productivity of the industrial sector is higher than the labor productivity of the service and agricultural sectors.

Fifth, based on GVA and employment figures, Russia is clearly a service sector driven economy. The share of GVA of the agricultural sector is significantly low, while the GVA share of the industrial sector has also declined over the years. With regards to employment, the results also indicate that the employment share has declined in of the agriculture and industrial sectors, but the employment share in the service sector has increased. Like Indonesia, trade openness in Russia has also declined from 60% in 1991 to around 47% in 2018. The labor productivity of the industrial sector is highest, followed by the service and agricultural sectors, respectively. Finally, we also consider the economic structure of South Africa, which is appealing much like Russia, except that trade openness for South Africa has increased consistently over the years.

Next, Table 2 presents the annual average growth rates of sectorial composition. The figures for all indicators are based on annual average growth rates from 1991 to 2018. The first row of Table 2 indicates that the GVA share of the agricultural sector has declined in BRICS and Indonesia, with highest rate of decline recorded in China and Russia. The GVA share of the industrial sector's growth rates also reveals a decline in Brazil, Russia and South Africa, almost stagnant in China and Indonesia, and a marginal increase by 0.01% in India. The third row clearly shows an increasing growth rate of GVA in the service sector for all six countries, with Russia recording the highest growth and Indonesia recording the lowest growth. The negative growth of GVA in the agricultural sector truly reflects in the share of employment in the agricultural sector. The fourth row indicates that the growth

rate of employment share to total employment has declined in all countries, with highest decline being recorded by Brazil (-3.0%), followed by Russia (-2.9%). Similarly, the growth rate of employment share in the industrial sector has been positive in three countries (India, Indonesia and China) and negative in the others (Russia, South Africa and Brazil). The growth rate of employment share in the service sector is positive for all six nations. with highest growth being reported in China, followed by Indonesia. The growth rate of labor productivity shows a diverse picture for all three sectors.

Table 2.
Annual Average Growth Rates of Sectorial Composition
in BRICS and Indonesia

The figures for all indicators are based on annual average growth rates from 1991 to 2018. This table indicates that the GVA share of the agricultural sector has declined in BRICS and Indonesia, with highest rate of decline being recorded by China and Russia. The results suggest an increasing growth rate of GVA in the service sector for all six countries, with Russia being highest and Indonesia being the lowest. The negative growth of GVA in the agricultural sector is truly reflect in the share of employment in the agricultural sector. The growth rate of employment share in the service sector is positive for all six nations, with the highest growth being reported in China, followed by Indonesia. The growth rate of labor productivity shows a diverse picture for all three sectors. Notes GVAA = gross value added in the agricultural sector, GVAI = gross value added in the industrial sector, GVAS = gross value added in the service sector, EA = employment in the agricultural sector, EI = employment in the industrial sector, ES = employment in the service sector, LPA = labor productivity in the agricultural sector, LPI = labor productivity in the industrial sector, LPS = labor productivity in the service sector.

	Brazil	China	India	Indonesia	Russia	South Africa
GVAA	-0.8	-4.3	-2.2	-1.4	-4.3	-2.0
GVAI	-1.7	0.0	0.1	0.0	-1.2	-1.1
GVAS	1.1	1.6	1.0	0.5	1.7	0.6
EA	-3.0	-2.9	-1.3	-2.0	-2.9	-2.5
EI	-0.3	1.1	1.8	1.7	-1.4	-0.7
ES	0.9	3.3	1.4	1.6	1.5	0.6
LPA	2.5	-1.4	-0.9	0.8	-0.9	1.0
LPI	-1.4	-1.1	-1.7	-1.4	0.3	-0.3
LPS	0.2	-1.6	-0.4	-1.0	0.3	0.0

Figure 1.
Trends of Labor Productivity in Agricultural Sector

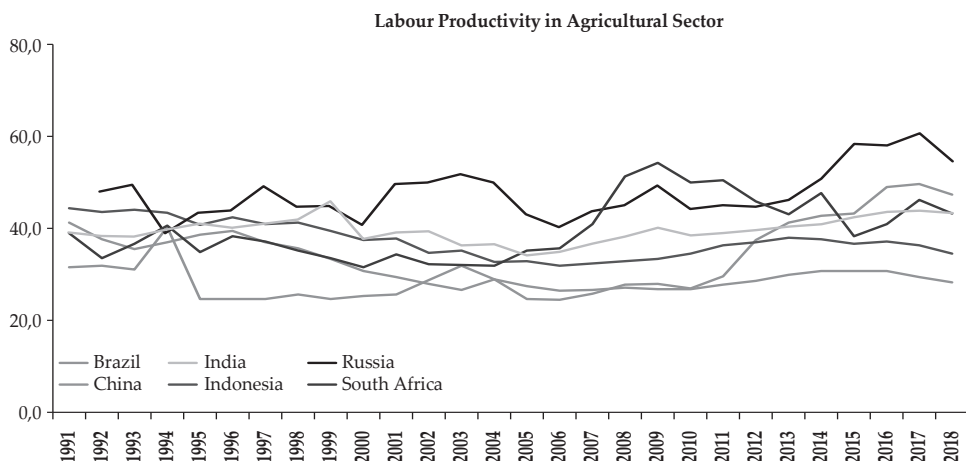

Figure 2.
Trends of Labor Productivity in Industrial Sector

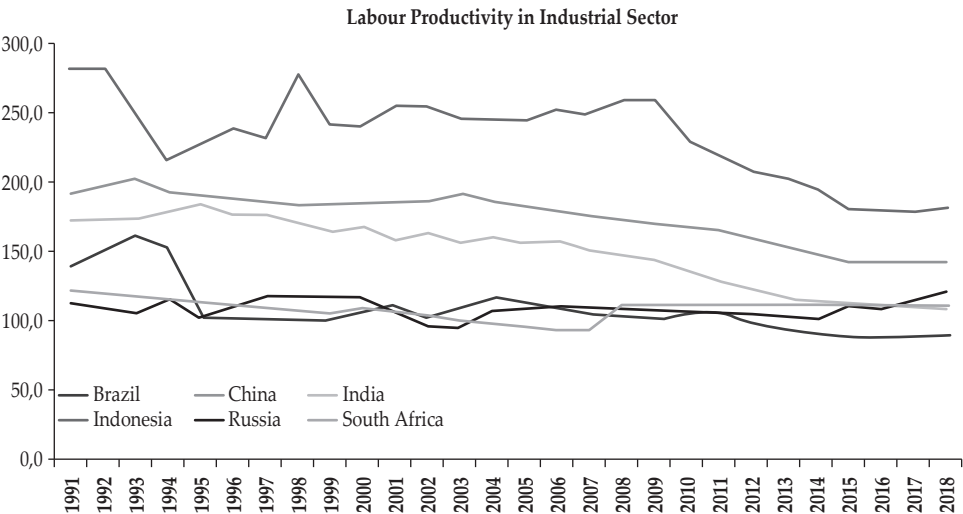

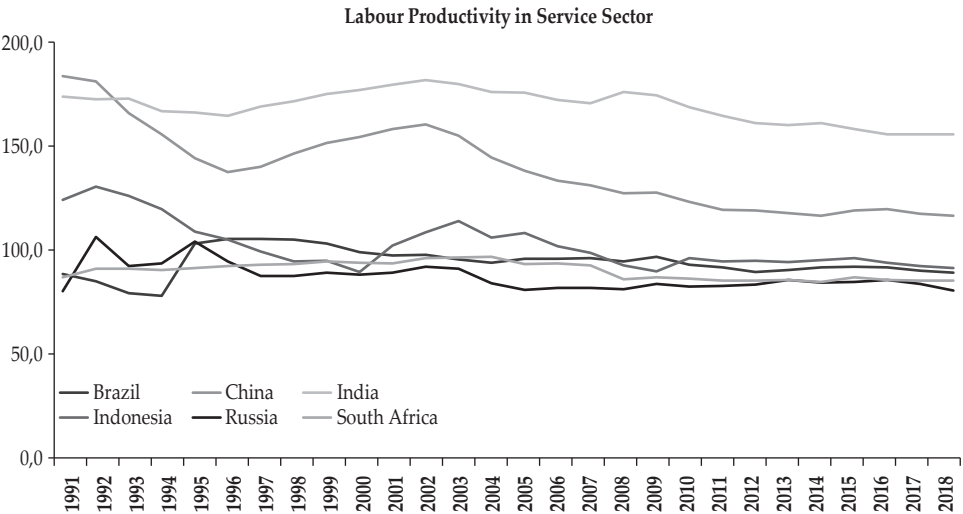

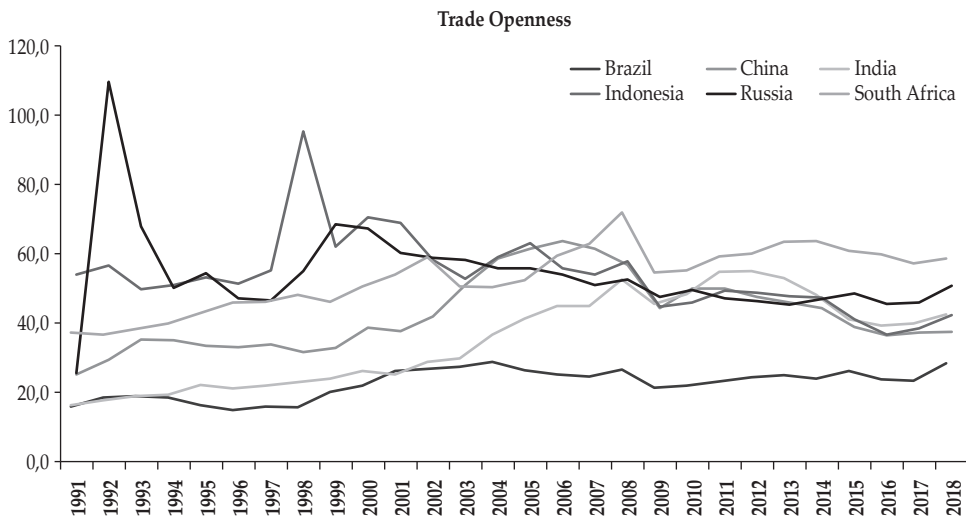

Figure 3.
Trends of Labor Productivity in Service Sector

Figures 1 to 3 demonstrate the trends in labor productivity for the three sectors. First, Figure 1 clearly shows that the labor productivity of the agricultural sector in Russia is the highest, followed by Brazil and South Africa. If we read Table 1, then, we notice that the shares of GVA and employment in the agricultural sector for these three countries are lower than those of China, India and Indonesia. Since the measurement of labor productivity is a ratio of GVA to per unit of labor,

therefore, although in Russia and Brazil, less number of labor force is engaged in the agricultural sector, their contribution to output is much higher. Second, labor productivity in the industrial sector clearly indicates that Indonesia outshines other countries and is followed by China. Though India ranks third, its labor productivity shows a deceleration trend from 1991 to 2018. Third, the trends of labor productivity in the service sector clearly indicate that India outperforms the other countries, and this finding is not surprising because India is considered one of the global service giants; this finding is consistent with Rath (2018).

Figure 4.
Trend of Trade Openness in BRICS and Indonesia

The Figure 4 shows the trends of trade openness in the six emerging countries. The figures reveal that both Russia and Indonesia were more open economies during 1991- 2000, but in the later years South Africa overtook both the countries. Similarly, China, which was showing a lower trade as a percentage of GDP in 1991, has significantly outperformed its counterparts after introducing many trade reforms. India, which was bottom among BRICS and Indonesia in 1991, has performed well by increasing its exports and imports volumes and values over the years. Brazil lags in trade openness among BRICS economies.

Table 3.
Panel Unit Root Test Results

This table presents the panel unit root test results used to examine the stationarity properties of the seven variables. Unit root tests of Im, Pesaran, Shin (IPS) (2003) and Pesaran (CIPS) (2007) are reported by considering both the intercept and intercept and trend in the test regressions. The null hypothesis for IPS and CIPS is that the variables contain unit roots. The test results indicate that we accept the null hypothesis in the majority of cases and arrive at a conclusion that all seven variables are nonstationary at level and stationary at first difference. Note that *** and ** represent 1% and 5% level of significance, respectively. The figures in parentheses indicate the probability values.

Variables	IPS		CIPS		lags
	C	C&T	C	C&T	
EA	1.77 (0.96)	1.01 (0.84)	-0.39 (0.35)	-0.65 (0.25)	0
EI	-1.04 (0.14)	-2.02** (0.02)	-0.73 (0.23)	2.61 (0.99)	0
ES	5.31 (1.00)	0.43 (0.66)	1.63 (0.94)	2.72 (0.99)	0
LPA	-3.70*** (0.00)	-0.73 (0.23)	-0.17 (0.43)	-0.16 (0.43)	1
LPI	0.52 (0.69)	-0.32 (0.37)	-1.20 (0.11)	-0.06 (0.47)	0
LPS	0.46 (0.67)	-3.75*** (0.00)	-1.99** (0.02)	-0.56 (0.28)	0
TO	-2.68*** (0.00)	-0.15 (0.43)	-0.64 (0.26)	-0.23 (0.41)	2

The panel unit root test results are reported in Table 3. These results are based on the IPS (Im et al., 2003) and CIPS (Pesaran, 2007) panel unit root tests under the null hypothesis that the variables contain unit roots. The results indicate that we accept the null hypothesis in the majority of cases and arrive at a conclusion that all seven variables are nonstationary at level and stationary at first difference.

Table 4.
Pedroni Panel Cointegration Test Results

This table presents the panel cointegration test results, which are based on the Pedroni (2004) test. Here, we controlled for both constant and trend (i.e. C&T) in the regressions. These results clearly show that only in Model I can we reject the null hypothesis of no cointegration. This implies that there exist a long-run cointegration relationship among employment, labor productivity and trade openness in the agricultural sector. Note that ***, **, and * represent 1%, 5% and 10% level of significance, respectively. The figures in parentheses indicate the probability values.

Models	Panel <i>v</i> -Statistic	Panel <i>rho</i> - Statistic	Panel <i>PP</i> - Statistic	Panel <i>ADH</i> - Statistic	Group <i>rho</i> - Statistic	Group <i>PP</i> - Statistic	Group <i>ADH</i> - Statistic
C&T							
Model I	10.89*** (0.00)	-0.13 (0.44)	-1.76** (0.03)	-2.26*** (0.01)	0.67 (0.74)	-1.50* (0.6)	-2.69*** (0.00)
Model II	-0.17 (0.56)	1.58 (0.94)	0.24 (0.59)	-1.46* (0.07)	1.78 (0.96)	0.11 (0.54)	-2.62 (0.00)
Model III	3.32*** (0.00)	1.42 (0.92)	0.72 (0.76)	0.84 (0.79)	2.09 (0.98)	2.09 (0.89)	2.09 (0.82)

Since we find the variables to be non-stationary at level, we can now check whether there is any evidence of a long-run relationship among employment, labor productivity and trade openness using the residual based cointegration test developed by Pedroni (2004). The results show that only in Model I can we reject the null hypothesis of no cointegration. This implies that there exist a long-run cointegration relationship among employment, labor productivity and trade openness in the agricultural sector. However, there is no cointegrating relationship among these three variables in the industrial and service sectors in BRICS and Indonesia.

Table 5.
Long-run Elasticities

This table indicates that labor productivity of the agricultural sector negatively affects employment, whereas trade openness positively affects employment in the agricultural sector. Note that ***, and * represent 1%, and 10% level of significance, respectively. The figures in parentheses indicate the probability values.

C&T	DOLS		FMOLS	
	LPA	TO	LPA	TO
Model I	-0.19*** (0.00)	0.03 (0.13)	-0.21*** (0.00)	0.03* (0.09)
Model II	---	---	---	---
Model III	---	---	---	---

Typically, after establishing the long-run relationship among variables, one would be interested in the long-run impact of explanatory variables on the dependent variable. We so in this study by estimating long-run elasticities using the DOLS and FMOLS estimators and report these results in Table 5. The study only presents the results obtained from the agricultural sector, as there was no evidence of a long-run relationship among the variables in the industrial and service sectors. The findings from Table 5 are as follows. First, a 1% increase in labor productivity in the agricultural sector leads to an average decline in employment in this sector by approximately 0.2%. The finding is consistent with theory that higher labor productivity leads to the substitution of capital-intensive production techniques for labor-intensive production techniques, which could potentially lead to mass destruction of jobs. The gain in productivity in the agricultural sector can lead to a reduction in employment as technological progress improves the efficiency of the production process, which is clearly visible in Table 2. Second, the long-run elasticity of employment in the agricultural sector with respect to a change in trade openness (0.03%) is positive.

Table 6.
Cross-sectional Dependence (CD) Test Results

This table presents the CD test results. These results show evidence of cross-sectional dependence in the model. Note that *** and ** represent 1% and 5% level of significance, respectively. The figures in parentheses indicate the probability values.

Variables	CD Test	Correlation	Absolute Correlation
EA	18.78*** (0.00)	0.92	0.92
EI	-2.26** (0.02)	-0.110	0.59
ES	18.88*** (0.00)	0.91	0.91
LPA	4.14*** (0.00)	0.20	0.29
LPI	5.94*** (0.00)	0.29	0.37
LPS	7.28*** (0.00)	0.35	0.42
TO	3.77** (0.00)	0.18	0.41

The panel cointegration test results based on the Pedroni (2004) test are only reliable in the absence of cross-sectional dependence (CD). Hence, we test for CD by using the Pesaran (2015) CD test.⁴ Table 6 presents these CD test results, and reveals the presence of cross-sectional dependence in the model.

Table 7.
Panel Cointegration Test Results Based on the Westerlund (2007) Test

This table shows the panel cointegration test results based on the Westerlund (2007) test, which takes into account cross-sectional dependence in the models. We test the null of no cointegration and the alternative hypothesis of cointegration. *** and **denote statistical significance at 1% and 5%, respectively. The figures in the parentheses indicate the probability values. Gt, Ga, Pt, and Pa are the four-panel cointegration statistics developed by Westerlund (2007). Gt and Ga are the groups mean tests. Pt and Pa are the panel tests.

Models	Gt	Ga	Pt	Pa
C&T				
Model I	-3.10** (0.05)	-3.49 (1.00)	-7.54** (0.02)	-3.50 (0.99)
Model II	-2.48 (0.55)	-7.44 (0.98)	-8.74*** (0.00)	-8.37 (0.78)
Model III	-1.24 (1.00)	-1.55 (1.00)	-4.24 (0.94)	-5.83 (0.95)

⁴ The CD test is particularly important because in the presence of CD, the residual based cointegration tests will be inefficient (see Westerlund, 2007).

Table 8.
Dumitrescu-Hurlin (D-H) Causality Test Results for Model I at First Difference

This table presents the Dumitrescu-Hurlin (2012) (D-H) panel causality test results. The D-H causality test is more effective in the presence of CD (see Dumitrescu and Hurlin, 2012). The results indicate that there is a unidirectional causality running from employment to labor productivity, from employment to trade openness, and from trade openness to labor productivity in the agricultural sector. Note that *** represents 1% level of significance. All variables are in first differences.

Models	W-Stat.	Zbar-Stat.	P-values
<i>LPA</i> → <i>EA</i>	1.89	-0.32	0.74
<i>EA</i> → <i>LPA</i>	4.77***	2.51***	0.01
<i>TO</i> → <i>EA</i>	1.72	-0.49	0.62
<i>EA</i> → <i>TO</i>	5.19***	2.93***	0.00
<i>TO</i> → <i>LPA</i>	4.93***	2.67***	0.01
<i>LPA</i> → <i>TO</i>	1.48	-0.72	0.46

After identifying the presence of cross-sectional dependence in data, we check the robustness of our cointegration test results by employing the Westerlund (2007) panel cointegration test. The test results are reported in Table 7. The results in Table 7 do not corroborate those presented in Table 4. That is, there is no evidence of a long-run relationship among employment, labor productivity and trade openness in the agricultural sector, as two out of four statistics are significant. Similar findings are also noticed in the manufacturing and service sector results. Finally, this study executes the D-H panel causality test. D-H test produces more consistent results in the presence of cross-section dependence and heterogeneity in the data (see Dumitrescu and Hurlin, 2012). The results based on the D-H causality test, which are reported in Table 8, show the evidence of a unidirectional causality running from employment to labor productivity, but not the other way round. Similarly, the results reveal that employment causes trade openness but not the reverse. Further, the pair-wise causality between trade openness and labor productivity shows a unidirectional causality running from trade openness to labor productivity in the agricultural sector. To summarize, based on our empirical results, we find little or no evidence on the nexus among employment, labor productivity and trade openness in BRICS and Indonesia. Our findings, to some extent, match earlier studies such as Liu and Trefler (2008), Gorg and Gorlish (2012), Geishecker and Gorg (2013), which also found minimal or no effect of trade openness on the labor market.

V. CONCLUSIONS

This paper examined the nexus among employment, labor productivity and trade openness in BRICS and Indonesia. Although there are reasonable number of studies, which empirically examined the relationship between employment and productivity, productivity and trade, and labor demand function, none examined the linkage among these three variables. To investigate this linkage, we picked BRICS and Indonesia because these six emerging countries have undergone several economic and trade reforms, which resulted in structural changes in their

economies. The study made use of annual data on trade openness, employment, and labor productivity of three key sectors (primary, secondary and tertiary) of these economies from 1991 to 2018. The results indicate that the economic structures of these countries have changed over the last three decades and employment and productivity alongside trade openness have played a significant role in these structural changes. Further, this study employed panel cointegration and causality tests to assess the long-and short-run relationships among trade openness, employment and productivity. The results derived from the panel cointegration tests revealed an existence of a long-run relationship in only the agricultural sector. The panel causality results also indicate a unidirectional causality running from employment to labor productivity growth in only the agricultural sector. Similarly, trade openness Granger causes employment; but based on the DOLS method, trade openness positively affects labor productivity in the long run. To sum up, we find little or no evidence on the nexus among employment, labor productivity and trade openness in BRICS and Indonesia.

From a policy perspective, it is imperative for BRICS and Indonesia to target employment generation by promoting trade openness. Although an increase in labor productivity adversely affects employment in the agricultural sector, boosting labor productivity in the service sector should be the key goal of policy makers, since all these countries are already moving towards service-driven economies. India is of course the exception, where labor productivity in the service sector is relatively high in comparison to Indonesia and other BRICS nations, but the service sector needs to absorb employment from the agricultural sector, where the bulk of the labor force is still in disguised unemployment.
